$$T = \frac{1}{k} \ln \left(\frac{h}{h - kP_0} \right)$$

Exercise

A certain body weighing 45 *lb*, is heated to a temperature of 300° . Then at $t = 0$ it is plunged into 100 *lb* of water at a temperature of 50° . Given that the specific heat of the body is $\frac{1}{9}$, find the formula for the temperature T of the body during its cooling.

Solution

$$H = mc\Delta t \quad c: \text{specific heat}$$

Let T_w : temperature of the water

$$\text{The amount of heat lost by the body is:} \quad 45 \left(\frac{1}{9} \right) (300 - T) = 5(300 - T)$$

$$\text{The amount of heat gained by the body is:} \quad 100(1)(T_w - 50) = 100(T_w - 50)$$

The 2 amounts are the same

$$5(300 - T) = 100(T_w - 50)$$

$$300 - T = 20T_w - 1000$$

$$T_w = \frac{1}{20}(1300 - T)$$

$$\text{Using Newton's law of cooling: } -\frac{dT}{dt} = k(T - T_w)$$

$$\frac{dT}{dt} = -k \left(T - \frac{1}{20}(1300 - T) \right)$$

$$= -k \left(T - 65 + \frac{1}{20} T \right)$$

$$= -\frac{21}{20} kT + 65k$$

$$\frac{dT}{dt} + \frac{21}{20} kT = 65k$$

$$e^{\int \frac{21}{20} k dt} = e^{\frac{21}{20} kt}$$

$$\int (65k) e^{\frac{21}{20} kt} dt = \frac{1,300}{21} e^{\frac{21}{20} kt}$$

$$T(t) = \frac{1}{e^{\frac{21}{20} kt}} \left(\frac{1,300}{21} e^{\frac{21}{20} kt} + C \right)$$

$$= \frac{1,300}{21} + C e^{-\frac{21}{20} kt}$$

$$T(0) = 300 \rightarrow 300 = \frac{1,300}{21} + C$$

$$\Rightarrow C = \frac{5,000}{21}$$

$$T(t) = \frac{1,300}{21} + \frac{5,000}{21} e^{-\frac{21}{20} kt}$$
