Exercise

Find a matrix P that orthogonally diagonalizes A , and determine $P^{-1}AP$ $A = \begin{pmatrix} 3 & 1 \\ 1 & 3 \end{pmatrix}$

Solution

$$\begin{aligned}
 \det(A - \lambda I) &= \begin{vmatrix} 3-\lambda & 1 \\ 1 & 3-\lambda \end{vmatrix} \\
 &= (3-\lambda)^2 - 1 \\
 &= \lambda^2 - 6\lambda + 8 = 0
 \end{aligned}$$

The eigenvalues are: $\lambda_1 = 2$ and $\lambda_2 = 4$

For $\lambda_1 = 2$, we have: $(A - \lambda_1 I)\vec{v}_1 = 0$

$$\begin{aligned}
 \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix} \rightarrow x + y = 0 \\
 \Rightarrow \underline{x = -y}
 \end{aligned}$$

Therefore, the eigenvector $\vec{v}_1 = \begin{pmatrix} -1 \\ 1 \end{pmatrix}$

For $\lambda_2 = 4$, we have: $(A - \lambda_2 I)\vec{v}_2 = 0$

$$\begin{aligned}
 \begin{pmatrix} -1 & 1 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} &= \begin{pmatrix} 0 \\ 0 \end{pmatrix} \rightarrow -x + y = 0 \\
 \Rightarrow \underline{x = y}

The eigenvalues are: $\lambda_1 = 3$ and $\lambda_2 = 10$

For $\lambda_1 = 3$, we have: $(A - \lambda_1 I)\vec{v}_1 = 0$

Therefore, the eigenvector $\vec{v}_1 = \begin{pmatrix} -2\sqrt{3} \\ 3 \end{pmatrix}$

$$A = \begin{pmatrix} -2 & 0 & -36 \\ 0 & -3 & 0 \\ -36 & 0 & -23 \end{pmatrix}$$

Solution

$$\begin{aligned} \det(A - \lambda I) &= \begin{vmatrix} -2-\lambda & 0 & -36 \\ 0 & -3-\lambda & 0 \\ -36 & 0 & -23-\lambda \end{vmatrix} \\ &= (-2-\lambda)(-3-\lambda)(-23-\lambda) - (36)(-3-\lambda)(36) \\ &= -(6+5\lambda+\lambda^2)(23+\lambda) + 3888 + 1296\lambda \\ &= -138 - 115\lambda - 23\lambda - 6\lambda - 5\lambda^2 - \lambda^3 + 3888 + 1296\lambda \\ &= \underline{-\lambda^3 - 28\lambda^2 + 1175\lambda + 3750 = 0} \end{aligned}$$

$$\lambda = -3$$

$$\begin{aligned} \lambda &= \frac{25 \pm \sqrt{625 + 5,000}}{-2} \\ &= \underline{\frac{25 \pm 75}{-2}} \end{aligned}$$

The eigenvalues are: $\lambda_1 = 25$, $\lambda_2 = -3$, and $\lambda_3 = -50$

For $\lambda_1 = 25$, we have: $(A - \lambda_1 I)\vec{v}_1 = 0$

For $\lambda_{3,4} = -25$, we have:

$$\begin{pmatrix} 18 & 24 & 0 & 0 \\ 24 & 32 & 0 & 0 \\ 0 & 0 & 18 & 24 \\ 0 & 0 & 24 & 32 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} 18 & 24 & 0 & 0 \\ 24 & 32 & 0 & 0 \\ 0 & 0 & 18 & 24 \\ 0 & 0 & 24 & 32 \end{pmatrix} \begin{aligned} & 3R_2 - 4R_1 \\ & 3R_4 - 4R_3 \end{aligned}$$

Find a matrix P that orthogonally diagonalizes A , and determine $P^{-1}AP$

$$A = \begin{pmatrix} 3 & 1 & 0 & 0 \\ 1 & 3 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Solution

$$\begin{aligned}
|A - \lambda I| &= \begin{vmatrix} 3-\lambda & 1 & 0 & 0 \\ 1 & 3-\lambda & 0 & 0 \\ 0 & 0 & -\lambda & 0 \\ 0 & 0 & 0 & -\lambda \end{vmatrix} \\

$$\begin{aligned}
 &= \lambda^2 (\lambda^2 - 6\lambda + 8) \\

Therefore, the matrix has eigenvalues

For $\lambda_3 = 2$, then $(A - 2I)\vec{v}_3 = 0$

For $\lambda_4 = 4$, then $(A - 4I)V_4 = 0$

Exercise

Find the eigenvalues of A and B and check the Orthogonality of their first two eigenvectors. Graph these eigenvectors to see the discrete sines and cosines:

$$A = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{bmatrix} \quad B = \begin{bmatrix} 1 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 1 \end{bmatrix}$$

The $-1, 2, -1$ pattern in both matrices is a “second derivative. Then $A\vec{x} = \lambda\vec{x}$ and $B\vec{x} = \lambda\vec{x}$ are like $\frac{d^2\vec{x}}{dt^2} = \lambda\vec{x}$. This has eigenvectors $x = \sin kt$ and $x = \cos kt$ that are the bases for Fourier series. The matrices lead to “discrete sines” and “discrete cosines” that are the bases for the discrete Fourier Transform. This DFT is absolutely central to all areas of digital signal processing.

Solution

The eigenvalues of A are $\lambda = 2 \pm \sqrt{2}$ and 2 .

Their sum is 6 (the trace of A) and their product is 4 (the determinant).

The eigenvector matrix S gives the “Discrete Sine Transform”.

$$S = \begin{pmatrix} 1 & \sqrt{2} & 1 \\ \sqrt{2} & 0 & -\sqrt{2} \\ 1 & -\sqrt{2} & 1 \end{pmatrix}$$

$$V_1 = \begin{pmatrix} 1 \\ \sqrt{2} \\ 1 \end{pmatrix} = \frac{\sqrt{2}}{2} \begin{pmatrix} \frac{\sqrt{2}}{2} \\ 1 \\ \frac{\sqrt{2}}{2} \end{pmatrix}$$

$$V_2 = \begin{pmatrix} \sqrt{2} \\ 0 \\ -\sqrt{2} \end{pmatrix} = \frac{\sqrt{2}}{2} \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$$

$$V_3 = \begin{pmatrix} 1 & 1 \\ -\sqrt{2} & 1 \\ 1 & 1 \end{pmatrix} = \frac{\sqrt{2}}{2} \begin{pmatrix} \frac{\sqrt{2}}{2} \\ -1 \\ \frac{\sqrt{2}}{2} \end{pmatrix}$$

The eigenvalues of B are $\lambda = 2 \pm \sqrt{2}$, 2 , 0 .

$$C = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & \sqrt{2}-1 & -1 & 1-\sqrt{2} \\ 1 & 1-\sqrt{2} & -1 & \sqrt{2}-1 \\ 1 & -1 & 1 & -1 \end{pmatrix}$$

Exercise

Suppose $A\bar{x} = \lambda\bar{x}$ and $A\bar{y} = 0\bar{y}$ and $\lambda \neq 0$. Then y is in the nullspace and \bar{x} is in the column space. They are perpendicular because _____. (why are these subspaces orthogonal?) If the second eigenvalue is a nonzero number β , apply this argument to $A - \beta I$. The eigenvalue moves to zero and the eigenvectors stay the same – so they are perpendicular.

Solution

Suppose that $A = A^T$ and $Ax = \lambda x$, $Ay = 0y$, and $\lambda \neq 0$. Then x is in the column space of A , and y is in the left nullspace of A since $N(A) = N(A^T)$. But $C(A)$ and $N(A^T)$ are orthogonal complements, so x and y are perpendicular.

If $Ay = \beta y$ with $\beta \neq \lambda$ then $(A - \beta I)x = (\lambda - \beta)x$ and $(A - \beta I)y = 0$. Since $\lambda - \beta \neq 0$ it follows that x is in the column space $A - \beta I$ and y is in the nullspace of $A - \beta I$, and $(A - \beta I)^T = A^T - \beta I^T = A - \beta I$, Therefore we can replace A with $A - \beta I$ in the argument of previous paragraph and it follows that x and y are perpendicular.

Exercise

Which of these classes of matrices do A and B belong to: Invertible, orthogonal, projection, permutation, diagonalizable, Markov?

$$A = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} \quad B = \frac{1}{3} \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}$$

Which of these factorizations are possible for A and B : LU , QR , ADP^{-1} , QDQ^T ?

Solution

Matrix A is invertible, orthogonal, a permutation matrix, diagonalizable, and Markov! (Everything but a projection).

Matrix A satisfies $A^2 = I$, $A = A^T$, and also $AA^T = I$. This means it is invertible, symmetric, and orthogonal. Since it is symmetric, it is diagonalizable (with real eigenvalues!). It is a permutation matrix by just looking at it. It is Markov since the columns add to 1. It is not a projection since $A^2 = I \neq A$.

All of the factorization are possible for it: LU and QR are always possible. PDP^{-1} is possible since it is diagonalizable, and QDQ^T is possible since it is symmetric.

Matrix B is a projection, diagonalizable, and Markov. It is not invertible, not orthogonal, and not a permutation.

B is a projection since $B^2 = B$, it is symmetric and thus diagonalizable, and it is Markov since the columns add to 1. It is not invertible since the columns are visibly linearly dependent, it is not orthogonal since the columns are far from orthonormal, and it's clearly not a permutation.

All the factorizations are possible for it: LU and QR are always possible. PDP^{-1} is possible since it is diagonalizable, and QDQ^T is possible since it is symmetric.

Exercise

True or false. Give a reason or a counterexample.

- a) A matrix with real eigenvalues and eigenvectors is symmetric.
- b) A matrix with real eigenvalues and orthogonal eigenvectors is symmetric.
- c) The inverse of a symmetric matrix is symmetric.
- d) The eigenvector matrix S of a symmetric matrix is symmetric.
- e) A complex symmetric matrix has real eigenvalues.
- f) If A is symmetric, then e^{iA} is symmetric.
- g) If A is Hermitian, then e^{iA} is Hermitian.
- h) An $n \times n$ matrix that is orthogonally diagonalizable must be symmetric.
- i) If $A^T = A$ and if vectors \vec{u} and \vec{v} satisfy $A\vec{u} = 3\vec{u}$ and $A\vec{v} = 4\vec{v}$, then $\vec{u} \cdot \vec{v} = 0$.
- j) An $n \times n$ symmetric matrix has n distinct real eigenvalues.
- k) For nonzero \vec{v} in \mathbb{R}^n , the matrix $\vec{v}\vec{v}^T$ is called a projection matrix.
- l) Every symmetric matrix is orthogonally diagonalizable.
- m) If $B = PDP^T$, where $P^T = P^{-1}$ and D is a diagonal matrix, then B is a symmetric matrix.
- n) An orthogonal matrix is orthogonally diagonalizable.
- o) The dimension of an eigenspace of a symmetric matrix equals the multiplicity of the corresponding eigenvalue.

Solution

a) **False.** Let $A = \begin{pmatrix} 1 & 2 \\ 1 & 0 \end{pmatrix}$

$$\text{Then } \det(A - \lambda I) = \begin{vmatrix} 1-\lambda & 2 \\ 1 & -\lambda \end{vmatrix} = \lambda^2 - \lambda - 2 = 0$$

So, A has eigenvalues $\lambda_1 = -1$ $\lambda_2 = 2$

The eigenvectors are: $V_1 = \begin{pmatrix} -1 \\ 1 \end{pmatrix}$ $V_2 = \begin{pmatrix} 2 \\ 1 \end{pmatrix}$ so both the eigenvalues and eigenvectors are real but

A is not symmetric.

b) True. If the matrix A has orthogonal eigenvectors $\vec{x}_1, \vec{x}_2, \dots, \vec{x}_n$ with eigenvalues

$\lambda_1, \lambda_2, \dots, \lambda_n$, we can define $\vec{s}_i = \frac{\vec{x}_i}{\|\vec{x}_i\|}$ for all i ; then $A\vec{s}_i = \lambda_i\vec{s}_i$ for all i and the \vec{s}_i are

orthonormal. Then we can diagonalize A as: $A = S\Lambda S^{-1}$ where the i^{th} column of S is \vec{s}_i , and Λ is

the diagonal matrix, so $S^T = S^{-1}$ and $A = S\Lambda S^T$.

$$\begin{aligned} A^T &= (S^T)^T \Lambda^T S^T \\ &= S\Lambda S^T \\ &= A \end{aligned}$$

So, A is symmetric.

c) True. If A is symmetric then it can be diagonalized by an orthogonal matrix Q , $A = QDQ^{-1}$, and then $A^{-1} = QD^{-1}Q^{-1} = QD^{-1}Q^T$. Since D^{-1} is still a diagonal matrix, it follows:

$$\begin{aligned} (A^{-1})^T &= QD^{-1}Q^T \\ &= A^{-1} \end{aligned}$$

d) False. The eigenvalues of $A = \begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$ are: $\lambda_1 = 0$ $\lambda_2 = 5$ and the eigenvectors are:

$$V_1 = \begin{pmatrix} 2 \\ -1 \end{pmatrix} \quad V_2 = \begin{pmatrix} 1 \\ 2 \end{pmatrix}.$$

We can diagonalize A with eigenvector matrix $S = \begin{pmatrix} 2 & 1 \\ -1 & 2 \end{pmatrix}$ which is not symmetric.

e) False. For example, $A = (i)$, the 1 by 1 matrix. The eigenvalue is i , it is not a real number.

f) True. $(e^{iA})^T = e^{(iA)^T} = e^{iA}$

g) False. $(e^{iA})^H = e^{(iA)^H} = e^{-iA^H} = e^{-iA}$. It is typically not the same as e^{iA} .

Taking $A = (1)$, the 1 by 1 matrix, would be an enough example because $e^{iA} = e^i$ which is not a real number.

h) An $n \times n$ matrix that is orthogonally diagonalizable must be symmetric.

i) If $A^T = A$ and if vectors \vec{u} and \vec{v} satisfy $A\vec{u} = 3\vec{u}$ and $A\vec{v} = 4\vec{v}$, then $\vec{u} \cdot \vec{v} = 0$

j) An $n \times n$ symmetric matrix has n distinct real eigenvalues.

- k) For nonzero \vec{v} in \mathbb{R}^n , the matrix $\vec{v}\vec{v}^T$ is called a projection matrix.
- l) Every symmetric matrix is orthogonally diagonalizable
- m) If $B = PDP^T$, where $P^T = P^{-1}$ and D is a diagonal matrix, then B is a symmetric matrix.
- n) An orthogonal matrix is orthogonally diagonalizable.
- o) The dimension of an eigenspace of a symmetric matrix equals the multiplicity of the corresponding eigenvalue.

Exercise

Find a symmetric matrix $\begin{pmatrix} 1 & b \\ b & 1 \end{pmatrix}$ that has a negative eigenvalue.

- a) How do you know it must have a negative pivot?
- b) How do you know it can't have two negative eigenvalues?

Solution

- a) The eigenvalues of that matrix are $1 \pm b$ / so take any $b < -1$ $b > 1$. In this case, the determinant is $1 - b^2 < 0$.
- b) The signs of the pivots coincide with the signs of the eigenvalues. Alternatively, the product of the pivots is the determinant, which is negative in this case. So, one of the two pivots must be negative.
- c) The product of the eigenvalues equals the determinant, which is negative in this case. So, precisely one numbers cannot have a negative product.

Exercise

Prove that A is any $m \times n$ matrix, then $A^T A$ has an orthonormal set of n eigenvectors

Solution

$(A^T A)^T = A^T (A^T)^T = A^T A$, then $A^T A$ is symmetric, therefore there is an eigenvector

$\vec{v}_1, \vec{v}_2, \dots, \vec{v}_n$ for $A^T A$.

Let $A\vec{v}_1 = \lambda_1 \vec{v}_1$ and $A\vec{v}_2 = \lambda_2 \vec{v}_2$

$$A\vec{v}_1 \cdot \vec{v}_2 = \vec{v}_1 \cdot A^T \vec{v}_2$$

$$A\vec{x} \cdot \vec{y} = \vec{x} \cdot A^T \vec{y}$$

$$A\vec{v}_1 \cdot \vec{v}_2 = \vec{v}_1 \cdot A\vec{v}_2$$

$$A^T = A \quad (\text{Since } A \text{ is a symmetric})$$

$$\lambda_1 \vec{v}_1 \cdot \vec{v}_2 = \vec{v}_1 \cdot \lambda_2 \vec{v}_2$$

$$\lambda_1 (\vec{v}_1 \cdot \vec{v}_2) = \lambda_2 (\vec{v}_1 \cdot \vec{v}_2)$$

$$(\lambda_1 - \lambda_2)(\vec{v}_1 \cdot \vec{v}_2) = 0$$

Since $\lambda_1 \neq \lambda_2$

$$\text{Therefore; } \underline{\vec{v}_1 \cdot \vec{v}_2 = 0}$$

Then the vectors $A\vec{v}_1, A\vec{v}_2, \dots, A\vec{v}_n$ are orthogonal

$$\begin{aligned} A\vec{v}_i \cdot A\vec{v}_j &= (A\vec{v}_i)^T A\vec{v}_j \\ &= \vec{v}_i^T A^T A\vec{v}_j \\ &= \vec{v}_i \cdot (A^T A\vec{v}_j) \\ &= \vec{v}_i \cdot (\lambda_j \vec{v}_j) \\ &= \lambda_j (\vec{v}_i \cdot \vec{v}_j) = 0 \end{aligned}$$

Example

Construct a 3 by 3 matrix A with no zero entries whose columns are mutually perpendicular. Compute $A^T A$. Why is it a diagonal matrix?

Solution

Consider the matrix $A = \begin{pmatrix} a & b & c \\ d & e & f \\ g & h & i \end{pmatrix}$ to be columns mutual perpendicular

$$\text{Let assume } A = \begin{pmatrix} 1 & 2 & 2 \\ 2 & -2 & 1 \\ -2 & -1 & 2 \end{pmatrix} \text{ then } A^T = \begin{pmatrix} 1 & 2 & -2 \\ 2 & -2 & -1 \\ 2 & 1 & 2 \end{pmatrix} \quad \text{or } A = \begin{pmatrix} 2 & 2 & -1 \\ -1 & 2 & 2 \\ 2 & -1 & 2 \end{pmatrix}$$

$$\begin{aligned} A^T A &= \begin{pmatrix} 1 & 2 & 2 \\ 2 & -2 & 1 \\ -2 & -1 & 2 \end{pmatrix} \begin{pmatrix} 1 & 2 & -2 \\ 2 & -2 & -1 \\ 2 & 1 & 2 \end{pmatrix} \\ &= \begin{pmatrix} 9 & 0 & 0 \\ 0 & 9 & 0 \\ 0 & 0 & 9 \end{pmatrix} \end{aligned}$$

$$(A^T A)_{ij} = (\text{column } i \text{ of } A)(\text{column } j \text{ of } A)$$

Exercise

Assuming that $b \neq 0$, find a matrix that orthogonally diagonalizes $\begin{bmatrix} a & b \\ b & a \end{bmatrix}$

Solution

$$\begin{aligned}\det(A - \lambda I) &= \begin{vmatrix} a - \lambda & b \\ b & a - \lambda \end{vmatrix} \\ &= (a - \lambda)^2 - b^2 \\ &= (a - \lambda - b)(a - \lambda + b) \\ &= (a - b - \lambda)(a + b - \lambda) = 0\end{aligned}$$

Therefore; the eigenvalues are: $\lambda_1 = a - b$ and $\lambda_2 = a + b$

Assume that $b \neq 0$.

For $\lambda_1 = a - b$, then $(A - (a - b)I)V_1 = 0$

The eigenvectors are: $V_1 = \begin{pmatrix} -1 \\ 1 \end{pmatrix}$

For $\lambda_2 = a + b$, then $(A - (a + b)I)V_2 = 0$

$$\begin{pmatrix} -b & b \\ b & -b \end{pmatrix} \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \rightarrow bx_2 = by_2$$

The eigenvectors are: $V_2 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$

Applying the Gram Schmidt process.

$$\vec{w}_2 = V_2 - \frac{\langle \vec{u}_1, V_2 \rangle}{\|V_2\|^2} V_2$$

$$\begin{aligned}

Exercise

Suppose A is a symmetric $n \times n$ matrix and B is any $n \times m$ matrix. Show that $B^T A B$, $B^T B$, and $B B^T$ are symmetric matrices.

Solution

A is a symmetric, that implies to $A = A^T$

$$\begin{aligned}
\left(B^T A B \right)^T &= B^T A^T \left(B^T \right)^T \\
&= B^T A B \quad \checkmark
\end{aligned}$$

Since, $\left(B^T A B \right)^T = B^T A B$, then $B^T A B$ is symmetric.

$$\begin{aligned}
\left(B^T B \right)^T &= B^T \left(B^T \right)^T \\
&= B^T B \quad \checkmark
\end{aligned}$$

Therefore, $B^T B$ is symmetric.

$$\begin{aligned}
\left(B B^T \right)^T &= \left(B^T \right)^T B^T \\
&= B B^T \quad \checkmark
\end{aligned}$$

Therefore, $B B^T$ is symmetric.

Exercise

Show that if A is an $n \times n$ symmetric matrix, then $(A\vec{x}) \cdot \vec{y} = \vec{x} \cdot (A\vec{y})$ for all $\vec{x}, \vec{y} \in \mathbb{R}^n$

Solution

A is a symmetric, that implies to $A = A^T$

$$\begin{aligned}(A\vec{x}) \cdot \vec{y} &= (A\vec{x})^T \cdot \vec{y} \\ &= \vec{x}^T A^T \cdot \vec{y} \\ &= \vec{x}^T A \cdot \vec{y} \\ &= \vec{x} \cdot (A\vec{y}) \quad \checkmark\end{aligned}$$

Exercise

Suppose A is invertible and orthogonally diagonalizable. Explain why A^{-1} is also orthogonally diagonalizable.

Solution

Since A is invertible, then $AA^{-1} = A^{-1}A = I$

And A is orthogonally diagonalizable, then $A = PDP^{-1}$

$$(A)^{-1} = (PDP^{-1})^{-1}$$

$$\begin{aligned}A^{-1} &= (P^{-1})^{-1} D^{-1} P^{-1} & D^{-1} &= D \text{ (is a diagonal matrix)} \\ &= PDP^{-1} \quad \checkmark\end{aligned}$$

Therefore, A^{-1} is also orthogonally diagonalizable.

Exercise

Suppose A and B are both orthogonally diagonalizable and $AB = BA$. Explain why AB is also orthogonally diagonalizable

Solution

Since A and B are both orthogonally diagonalizable, and A and B are symmetric, then

$$A = A^T \quad \& \quad B = B^T$$

If $AB = BA$, then

$$\begin{aligned}(AB)^T &= (BA)^T \\ &= A^T B^T & A \text{ and } B \text{ are symmetric} \\ &= AB \quad \checkmark\end{aligned}$$

Therefore, AB is also orthogonally diagonalizable

Exercise

Let $A = PDP^{-1}$, where P is orthogonal and D is diagonal, let λ be an eigenvalue of A of multiplicity k . Then λ appears k times on the diagonal of D . Explain why the dimension of the eigenspace for λ is k .

Solution

The columns of P are linearly independent eigenvectors by the **diagonalization** theorem corresponding to the eigenvalues λ of A .

Since D is a diagonal with the eigenvalues λ . when the eigenvalues λ is of multiplicity k , then λ appears k times on the diagonal of D .

So, P has exactly k columns of eigenvectors corresponding to the eigenvalues λ .

Therefore, the k columns form a basis for the eigenspace.

Exercise

Suppose $A = PUP^{-1}$, where P is orthogonal and U is an upper triangular. Show that if A is symmetric, then U is symmetric and hence is actually a diagonal matrix.

Solution

Given: $A = PUP^{-1}$

If A is symmetric, then $A = A^T$

$$A = PUP^{-1}$$

$$P^{-1}AP = P^{-1}PUP^{-1}P$$

$$U = P^{-1}AP$$

Since P is orthogonal, then

$$U = P^{-1}AP = P^T AP$$

$$U^T = (P^T AP)^T$$

$$= P^T A^T (P^T)^T \quad A \text{ is symmetric}$$

$$= P^T AP$$

That implies that U is symmetric

Since U is an upper triangular and symmetric, then the entries above and below the main diagonal must be equal to zeros.

Therefore, U is a diagonal matrix.

Exercise

Let \vec{u} be a unit vector in \mathbb{R}^n , and let $B = \vec{u} \vec{u}^T$.

- a) Given $\vec{x} \in \mathbb{R}^n$, compute $B\vec{x}$ and show that $B\vec{x}$ is the orthogonal projection of \vec{x} onto \vec{u} .
- b) Show that B is a symmetric matrix and $B^2 = B$.
- c) Show that \vec{u} is an eigenvector of B . What is the corresponding eigenvalue?

Solution

- a) Given $\vec{x} \in \mathbb{R}^n$

$$\begin{aligned} B\vec{x} &= (\vec{u} \vec{u}^T) \vec{x} \\ &= \vec{u} (\vec{u}^T \vec{x}) \\ &= (\vec{u}^T \vec{x}) \vec{u} \quad \vec{u}^T \vec{x} : \text{scalar} \\ &= (\vec{x} \cdot \vec{u}) \vec{u} \end{aligned}$$

Given that \vec{u} is a unit vector in \mathbb{R}^n , then $B\vec{x}$ is the orthogonal projection of \vec{x} onto \vec{u} .

$$\begin{aligned} b) \quad B^T &= (\vec{u} \vec{u}^T)^T \\ &= (\vec{u}^T)^T \vec{u}^T \\ &= \vec{u} \vec{u}^T \\ &= B \quad \checkmark \end{aligned}$$

Therefore, B is symmetric.

$$\begin{aligned} B^2 &= (\vec{u} \vec{u}^T)^2 \\ &= (\vec{u} \vec{u}^T) (\vec{u} \vec{u}^T) \\ &= \vec{u} (\vec{u}^T \vec{u}) \vec{u}^T \quad \vec{u}^T \vec{u} = 1 \\ &= \vec{u} \vec{u}^T \\ &= B \quad \checkmark \end{aligned}$$

Therefore, B^2 is symmetric.

- c) Since $\vec{u}^T \vec{u} = 1$, then

$$\begin{aligned} B\vec{u} &= (\vec{u} \vec{u}^T) \vec{u} \\ B\vec{u} &= \vec{u} (\vec{u}^T \vec{u}) \end{aligned}$$

$$\begin{aligned}
&= \vec{u}(1) \\
&= \vec{u} \mid
\end{aligned}$$

Therefore, \vec{u} is an eigenvector of B with the corresponding eigenvalue 1.

Exercise

Let B be an $n \times n$ symmetric matrix such that $B^2 = B$. Any such matrix is called a **projection matrix** (or an *orthogonal projection matrix*). Given any $\vec{y} \in \mathbb{R}^n$, let $\hat{y} = B\vec{y}$ and $\vec{z} = \vec{y} - \hat{y}$.

- a) Show that \vec{z} is orthogonal to \hat{y} .
- b) Let W be the column space of B . Show that \vec{y} is the sum of a vector in W and a vector in W^\perp . Why does this prove that $B\vec{y}$ is the orthogonal projection of \vec{y} onto the column space of B ?

Solution

Since B is symmetric, then $B = B^T$

Given too, that $B^2 = B$ which is symmetric.

$$\hat{y} = B\vec{y}$$

$$\begin{aligned}
a) \quad \vec{z} \cdot \hat{y} &= (\vec{y} - \hat{y}) \cdot B\vec{y} \\
&= \vec{y} \cdot (B\vec{y}) - \hat{y} \cdot (B\vec{y}) \\
&= \vec{y}^T \cdot (B\vec{y}) - (B\vec{y})^T \cdot (B\vec{y}) \\
&= \vec{y}^T \cdot B\vec{y} - \vec{y}^T B^T \cdot B\vec{y} \\
&= \vec{y}^T \cdot B\vec{y} - \vec{y}^T B \cdot B\vec{y} \quad B^2 = B \\
&= \vec{y}^T B \vec{y} - \vec{y}^T B \vec{y} \\
&= 0 \mid
\end{aligned}$$

Therefore, \vec{z} is orthogonal to \hat{y}

- b) Since W be the column space of B , then $W = \text{Col}(B)$ has the form $B\vec{u}$ (for some \vec{u})

$$\begin{aligned}
(\vec{y} - \hat{y}) \cdot (B\vec{u}) &= B(\vec{y} - \hat{y}) \cdot \vec{u} \\
&= (B\vec{y} - B\hat{y}) \cdot \vec{u} \\
&= (B\vec{y} - BB\vec{y}) \cdot \vec{u} \quad B^2 = B \\
&= (B\vec{y} - B\vec{y}) \cdot \vec{u} \\
&= 0 \mid
\end{aligned}$$

Therefore, $(\vec{y} - \hat{y})$ is in W^\perp , and the decomposition $\vec{y} = \hat{y} + (\vec{y} - \hat{y})$ expresses \vec{y} as the sum of a vector in W and a vector in W^\perp .

By the orthogonal Decomposition, this decomposition is unique, and so \hat{y} must be orthogonal projection of \vec{y} onto the column space of $B(W)$
