## Section 2.7 – Euler's & Runge-Kutta Methods

Euler's method named after Leonhard Euler is an example of a fixed-step solver.

Euler's method is a first-order numerical procedure for solving ordinary differential equations (*ODE*s) with a given initial value. It is the most basic kind of explicit method for numerical integration of ordinary differential equations.

$$y' = f(x, y)$$
  $y(x_0) = y_0$ 

The setting size:  $h = \frac{b-a}{k} > 0$ ;  $k \in \mathbb{N}$ 

Then, 
$$x_0 = a$$
  
 $x_1 = x_0 + h = a + h$   
 $x_k = x_{k-1} + h = a + kh$   
Last point  $x_k = a + kh = b$ 

By the definition of the derivative:

$$y'(x_k) \approx \frac{y(x_{k+1}) - y(x_k)}{h}$$
$$y'(x_k) \approx \frac{y_{k+1} - y_k}{h} = f(x_k, y_k) : slope$$

The tangent line at the point  $(x_0, y(x_0))$  is:

$$y_{k+1} = y_k + h.f(x_k, y_k)$$
$$y_{k+1} = y_k + \Delta x_{step}.f(x_k, y_k)$$

This method is known as *Euler's Method* with step size *h*.

### **Example**

Compute the first four step in the Euler's method approximation to the solution of y' = y - x with y(1) = 1, using the step size h = 0.1. Compare the result with the actual solution to the initial value problem.

#### Solution

$$y(1) = 1 \Rightarrow x_0 = 1$$
 and  $y_0 = 1$ 

The *first* step:

$$y_1 = y_0 + h(y_0 - x_0)$$

$$= 1 + 0.1(1 - 1)$$

$$= 1$$

$$x_1 = x_0 + h = 1 + 0.1 = 1.1$$

The *second* step:

$$y_2 = y_1 + h(y_1 - x_1)$$

$$= 1 + 0.1(1 - 1.1)$$

$$= 0.99$$

$$x_2 = x_1 + h = 1.1 + 0.1 = 1.2$$

The *third* step:

$$y_3 = y_2 + h(y_2 - x_2)$$

$$= 0.99 + 0.1(0.99 - 1.2)$$

$$= 0.969$$

$$x_3 = x_2 + h = 1.2 + 0.1 = 1.3$$

The *fourth* step:

$$y_4 = y_3 + h(y_3 - x_3)$$

$$= 0.969 + 0.1(0.969 - 1.3)$$

$$= 0.9359$$

$$x_3 = x_2 + h = 1.3 + 0.1 = 1.4$$

The exact solution to y' = y - x is  $y(x) = 1 + x - e^{x-1}$ 

$x_k$	$y_k$ : Euler's	$y_k$ - exact	Error
1.0	1.0	1.0	0
1.1	1.0	0.9948	-0.0052
1.2	0.990	0.9786	-0.0114
1.3	0.969	0.9501	-0.0189
1.4	0.9359	0.9082	-0.0277

## **Runge-Kutta Methods**

Like Euler's method, the Runge-Kutta methods are fixed-step solvers.

### The Second-Order Runge-Kutta Method

The Second-Order Runge-Kutta method is also known as the improved Euler's method.

Starting from the initial value point  $(x_0, y_0)$ , we compute two slopes:

$$\begin{aligned} s_1 &= f\left(t_0^-, y_0^-\right) \\ s_2 &= f\left(t_0^- + h_0^-, y_0^- + h s_1^-\right) \\ y_1 &= y_0^- + h \frac{s_1^- + s_2^-}{2} \end{aligned}$$

But an analysis using Taylor's theorem reveals that there is an improvement in the estimate for the truncation error.

For the Second-Order Runge-Kutta method, we have

$$\left| y(t_1) - y_1 \right| \le Mh^3$$

The constant M depends on the function f(t, y).

The Second-Order Runge-Kutta method is controlled by the cube of the step size instead of the square.

Input 
$$t_0$$
 and  $y_0$ 
For  $k = 1$  to  $N$ 

$$s_1 = f\left(t_{k-1}, y_{k-1}\right)$$

$$s_2 = f\left(t_{k-1} + h, y_{k-1} + hs_1\right)$$

$$y_k = y_{k-1} + h\frac{s_1 + s_2}{2}$$

$$t_k = t_{k-1} + h$$

## Example

Compute the first four step in the Second-Order Runge-Kutta method approximation to the solution of y' = y - t with y(1) = 1, using the step size h = 0.1. Compare the result with the actual solution to the initial value problem.

#### **Solution**

$$\Rightarrow t_0 = 1 \text{ and } y_0 = 1$$
The first step:
$$s_1 = f(t_0, y_0)$$

$$= y_0 - t_0$$

$$= 1 - 1$$

$$= 0$$

$$s_2 = f(t_0 + h, y_0 + hs_1)$$

$$= (y_0 + hs_1) - (t_0 + h)$$

$$= (1 + .1(0)) - (1 + .1)$$

$$= 1 - 1.1$$

$$= -0.1$$

$$y_1 = y_0 + h \frac{s_1 + s_2}{2}$$

$$= 1 + 0.1(\frac{0 - 0.1}{2})$$

$$= \frac{0.995}{1}$$

$$t_1 = t_0 + h$$

$$= 1 + 0.1$$

$$= 1.1$$

The *second* step:

$$\begin{split} s_1 &= y_1 - t_1 = 0.995 - 1.1 = -0.105 \\ s_2 &= \left(y_1 + h s_1\right) - \left(t_1 + h\right) = \left(0.995 + .1(-0.105)\right) - \left(1.1 + .1\right) = -.2155 \\ y_2 &= y_1 + h \frac{s_1 + s_2}{2} = .995 + 0.1\left(\frac{-.105 - .2155}{2}\right) = .978975 \\ t_2 &= t_1 + h = 1.1 + .1 = 1.2 \end{split}$$

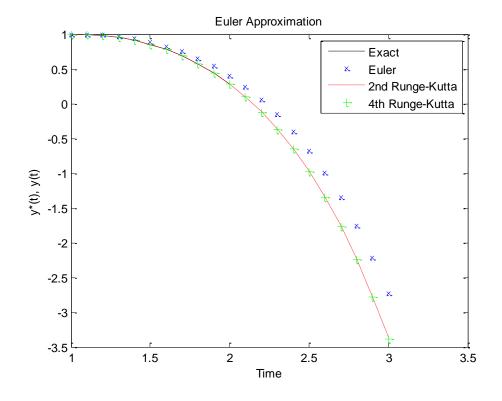

The *third* step:

$$\begin{split} s_1 &= y_2 - t_2 = 0.978975 - 1.2 = -0.221025 \\ s_2 &= \left(y_2 + hs_1\right) - \left(t_2 + h\right) = \left(0.978975 + .1(-0.221025)\right) - \left(1.2 + .1\right) = -.3431275 \\ y_3 &= y_2 + h\frac{s_1 + s_2}{2} = .978975 + 0.1\left(\frac{-.221025 - .3431275}{2}\right) = 0.9507673 \\ t_3 &= t_2 + h = 1.3 \end{split}$$

The *fourth* step:

$$\begin{split} s_1 &= y_3 - t_3 = 0.9507673 - 1.3 = -0.3492327 \\ s_2 &= \left(y_3 + hs_1\right) - \left(t_3 + h\right) = \left(0.9507673 + .1(-0.3492327)\right) - \left(1.3 + .1\right) = -.48415597 \\ y_4 &= y_3 + h\frac{s_1 + s_2}{2} = .9507673 + 0.1\left(\frac{-.3492327 - .48415597}{2}\right) = 0.9090979 \\ t_4 &= t_3 + h = 1.4 \end{split}$$

$t_k$	$y_k$ : Runge-Kutta	$y_k$ - Exact	Runge-Kutta Error	Euler's Error
1.0	1.0	1.0	0	0
1.1	0.9950000	0.994829081	-0.000170918	-0.0052
1.2	0.9789750	0.978597241	-0.000377758	-0.0114
1.3	0.9507673	0.950141192	-0.000626182	-0.0189
1.4	0.9090979	0.908175302	-0.000922647	-0.0277

## Fourth-Order Runge-Kutta Method

This method is the most commonly used solution algorithm. For most equations and systems it is suitably fast and accurate.

Starting from the initial value point  $(t_0, y_0)$ , we compute two slopes:

$$\begin{split} s_1 &= f\left(t_0, y_0\right) \\ s_2 &= f\left(t_0 + \frac{h}{2}, \ y_0 + \frac{h}{2}s_1\right) \\ s_3 &= f\left(t_0 + \frac{h}{2}, \ y_0 + \frac{h}{2}s_2\right) \\ s_4 &= f\left(t_0 + h, \ y_0 + hs_3\right) \\ y_1 &= y_0 + h\frac{s_1 + 2s_2 + 2s_3 + s_4}{6} \end{split}$$

## **Example**

Compute the first four step in the Second-Order Runge-Kutta method approximation to the solution of y' = y - t with y(1) = 1, using the step size h = 0.1. Compare the result with the actual solution to the initial value problem.

#### Solution

$$\Rightarrow t_0 = 1 \text{ and } y_0 = 1$$
The first step:
$$s_1 = f(t_0, y_0)$$

$$= 1 - 1$$

$$= 0$$

$$s_2 = f(t_0 + \frac{h}{2}, y_0 + \frac{h}{2}s_1)$$

$$= f(1.05, 1)$$

$$= 1 - 1.05$$

$$= -0.05$$

$$s_3 = f(t_0 + \frac{h}{2}, y_0 + \frac{h}{2}s_2)$$

$$= f(1.05, .9975)$$

$$= .9975 - 1.05$$

$$= -0.0525$$

$$s_4 = f(t_0 + h, y_0 + hs_3)$$

$$= f (1.1,.99475)$$

$$= .99475 - 1.1$$

$$= -0.10525$$

$$y_1 = y_0 + h \frac{s_1 + 2s_2 + 2s_3 + s_4}{6}$$

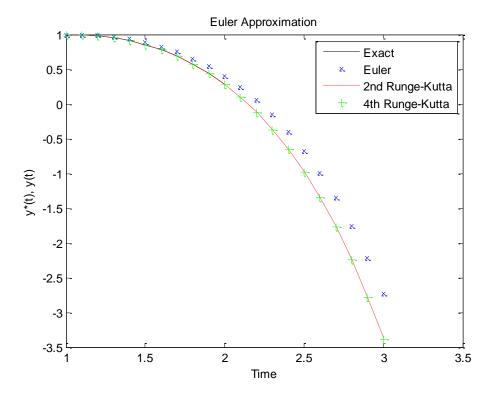

$$= 1 + 0.1 \left( \frac{0 + 2(-.05) + 2(-.0525) + (-.10525)}{6} \right)$$

$$= 0.99482916667$$

$$t_1 = t_0 + h$$

$$= 1.1$$

$t_k$	$y_k$ : Runge-Kutta	$y_k$ - Exact	Runge-Kutta Error
1.0	1.0	1.0	0
1.1	0.994829167	0.994829081	-0.000000086
1.2	0.978597429	0.978597241	0.000000295
1.3	0.950141502	0.950141192	-0.000000310

# **Exercises** Section 2.7 – Euler's & Runge-Kutta Methods

Calculate the first five iterations of Euler's method with step h = 0.1 of

- 1. y' = ty y(0) = 1
- 2. z' = x 2z z(0) = 1
- 3. z' = 5 z z(0) = 0
- **4.** Given: y' + 2xy = x y(0) = 8
  - a) Use a computer and Euler's method to calculate three separate approximate solutions on the interval [0, 1], one with step size h = 0.2, a second with step size h = 0.1, a second with step size h = 0.05.
  - b) Use the appropriate analytic to compute the exact solution
  - c) Plot the exact solution and approximate solutions as discrete points.
- 5. Given:  $y' + 2y = 2 e^{-4t}$  y(0) = 1
  - a) Solve the differential equation
  - b) Use Euler's method and Runge-Kutta methods to calculate three separate approximate solutions on the interval [0, 1], one with step size h = 0.2, a second with step size h = 0.1, a second with step size h = 0.05. Plot the exact solution and approximate solutions as discrete points.
- **6.** Given:  $z' 2z = xe^{2x}$  z(0) = 1
  - a) Use a computer and Euler's method to calculate three separate approximate solutions on the interval [0, 1], one with step size h = 0.2, a second with step size h = 0.1, a third with step size h = 0.05.
  - b) Use the appropriate analytic to compute the exact solution
  - c) Plot the exact solution and approximate solutions as discrete points.
- 7. Consider the initial value problem y' = 12y(4 y) y(0) = 1Use Euler's method with step size h = 0.04 to sketch solution on the interval  $\begin{bmatrix} 0, 2 \end{bmatrix}$
- You've seen that the error in Euler's method varies directly as the first power of the step size  $\left(i.e \ E_h \approx \lambda h\right)$ . This makes Euler's method an order to halve the error? How does this affect the number of required iterations?
- 9. Use Euler's method to provide an approximate solution over the given time interval using the given steps sizes. Provide a plot of v versus y for each step size

81

$$y'' + 4y = 0$$
,  $y(0) = 4$ ,  $y'(0) = 0$ ,  $[0, 2\pi]$ ;  $h = 0.1, 0.01, 0.001$ 

**10.** Given  $z' + z = \cos x$  z(0) = 1

- a) Use a computer and Runge-Kutta method to calculate three separate approximate solutions on the interval [0, 1], one with step size h = 0.2, a second with step size h = 0.1, a second with step size h = 0.05.
- b) Use the appropriate analytic to compute the exact solution
- c) Plot the exact solution and approximate solutions as discrete points.

**11.** Given  $x' = \frac{t}{x}$  x(0) = 1

- a) Use a computer and Runge-Kutta method to calculate three separate approximate solutions on the interval [0, 1], one with step size h = 0.2, a second with step size h = 0.1, a second with step size h = 0.05.
- b) Use the appropriate analytic to compute the exact solution
- c) Plot the exact solution and approximate solutions as discrete points.
- **12.** Consider the initial value problem  $y' = \frac{t}{y^2}$  y(0) = 1

Use Runge-Kutta method with step size h = 0.04 to sketch solution on the interval [0, 2]

13. Consider the initial value problem  $y' - y = -\frac{1}{2}e^{t/2}\sin 5t + 5e^{t/2}\cos 5t$  y(0) = 0

Use Runge-Kutta method with step size h = 0.05 to sketch solution on the interval [0, 5]
